THE PAULI OPERATOR CORRECTION IN THE EFFECTIVE AN INTERACTION

by

Jaleh Owliaei

A Thesis
Submitted to the
Faculty of The Graduate College
in partial fulfillment of the
requirement for the
Degree of Master of Arts
Department of Physics

Western Michigan University
Kalamazoo, Michigan
April 1985
Hypernuclear structure calculations performed for $^6_{A} Li$, $^7_{A} Li$, and $^{16}_{A} O$ have reproduced the $I_A = 1$ levels inferred from the recent $(k^-,\pi^-)$ reactions. However the $I_A = 0^+$ groundstate of $^{16}_{A} O$ is overbound by 6 MeV in these calculations, indicating a density dependence in the effective AN interaction in the interior of the heavier system. In this work corrections to the $^{16}_{A} O$ effective interaction are introduced in terms of a Brueckner-Goldstone G-matrix with a modified Pauli operator. The G-matrix of $^{16}_{A} O$ derived from that of $^6_{A} Li$ with the corrected Pauli operator results in an improvement of about one-half MeV for the groundstate of $^{16}_{A} O$. This makes the inclusion of the repulsive three-body forces, which has been neglected in the present calculations, more urgent. Since the number of ANN interactions in $^{16}_{A} O$ are ten times more than those in $^6_{A} Li$, these three-body interactions would improve the overbinding in $^{16}_{A} O$ with little effect on $^6_{A} Li$.

INFORMATION TO USERS

This reproduction was made from a copy of a document sent to us for microfilming. While the most advanced technology has been used to photograph and reproduce this document, the quality of the reproduction is heavily dependent upon the quality of the material submitted.

The following explanation of techniques is provided to help clarify markings or notations which may appear on this reproduction.

1. The sign or “target” for pages apparently lacking from the document photographed is “Missing Page(s)”. If it was possible to obtain the missing page(s) or section, they are spliced into the film along with adjacent pages. This may have necessitated cutting through an image and duplicating adjacent pages to assure complete continuity.

2. When an image on the film is obliterated with a round black mark, it is an indication of either blurred copy because of movement during exposure, duplicate copy, or copyrighted materials that should not have been filmed. For blurred pages, a good image of the page can be found in the adjacent frame. If copyrighted materials were deleted, a target note will appear listing the pages in the adjacent frame.

3. When a map, drawing or chart, etc., is part of the material being photographed, a definite method of “sectioning” the material has been followed. It is customary to begin filming at the upper left hand corner of a large sheet and to continue from left to right in equal sections with small overlaps. If necessary, sectioning is continued again—beginning below the first row and continuing on until complete.

4. For illustrations that cannot be satisfactorily reproduced by xerographic means, photographic prints can be purchased at additional cost and inserted into your xerographic copy. These prints are available upon request from the Dissertations Customer Services Department.

5. Some pages in any document may have indistinct print. In all cases the best available copy has been filmed.

CHAPTER I

INTRODUCTION

The central problem of nuclear physics is to understand and describe the structure of nuclei in terms of the particles forming them and the interactions among these particles. In this study some aspects of $^{16}_A$ nucleus are examined. Thus it is assumed that the constituent baryons are protons, neutrons and a $\Lambda$-hyperon. An effective interaction among these particles is formulated in terms of the Brueckner-Goldstone theory of nuclear matter.

Hypermultiplets - Why Study Them?

Nuclear force with its short range attraction ($r \approx 2$ fm), hard core repulsion ($r \approx 0.5$ fm), non-central, spin dependent nature and other peculiarities appears to be more complex than other known fundamental forces. Complicated forces in one well investigated case, that of chemical forces between atoms, is well understood in terms of internal structure of atoms. This idea suggests that the complexity of nuclear force might be a manifestation of internal structure and fundamental forces acting within nucleons. Internal nuclear motions can give rise to the excited nucleons (Gottfried & Weisskopf, 1984)

One uses the term "baryon" for fermions that interact via the strong interaction. The existence of baryons other than nucleons was first inferred from the analysis of high energy cosmic rays.
They are short-lived particles and carry different charges, but all are an integer multiple of the charge of electron. Among these baryons was found a neutral massive particle which decays into proton and pion, but rather slowly. This particle was identified as lambda particle. Its lifetime is $2.6 \times 10^{-10}$ sec. This is much longer than $10^{-23}$ sec, typical of strong interaction; it is rather close to $10^{-8}$ sec, the order of weak interaction lifetime. Gellmann and Nishijima speculated that $\Lambda$ has a property that proton and neutron do not have, and the decay $\Lambda \rightarrow p + \pi$ violates conservation of this property, which is called "$\text{strangeness}$" $S$. Strangeness is conserved in strong interaction but could be changed by 1 in weak interaction. $\Lambda$ is defined as having $S = -1$ (Dalitz, 1981; Soga, 1983).

Later eight of these particles were grouped into a baryon octet, based on their 3-quark structure. Particles with no s-quarks in their wave function have $S = 0$, and these are proton and neutron. The other particles in baryon octet have one or two s-quarks in their structure and have $S$ different from zero. Particles with $S = -1$, which are $\Lambda$ and $\Sigma$ baryons are called Y-particles. The $S \neq 0$ particles are collectively called "$\text{hyperons}"$ or "$\text{strange particles}$".

The charge equation is modified as:

$$Q = I_3 + \frac{1}{2} Y, \quad Y = B + S + C$$

where inclusion of $S$ and $C$ now gives correct results for neutral $\Lambda$-particle as well as the rest of baryons. Here $B$ is the
"baryon" number which is 1 for all baryons, Q is the modified charge, \( I_3 \) is the "isospin projection", S is strangeness, C is "charm" and \( Y \) is called "hypercharge". This general charge equation which now encompasses all the states, introduces a new set of quantum numbers. These numbers, far from being an artifice (to save the charge equation), each has its own significance in subnuclear physics. Some properties of the baryon octet are summarised in the following diagrams: (Gottfried & Weisskopf, 1984; Soga, 1983, 1984).

\[

\]

![Figure 2. Quark structure of baryons](image)
A hypernucleus is a nucleus in which one or more nucleons are replaced by hyperons. For example, $\Lambda$-hyperons are known to form particle stable bound states with all the stable nuclei as well as with some nuclei which are normally not particle stable. These $\Lambda$-nucleus systems are called $\Lambda$-hypernuclei, indicated by $^{A}_{Z}$, in which $Z$ is the symbol for the nuclear charge and $A$ is the mass number.

Most of our knowledge about hyperon-nucleon interactions stems from the hyperon-nucleon binding energies. This is so because the short life time of hyperons make the hyperon-nucleon scattering experiments very difficult.

Since the path lengths traversed by hyperon before decay is so short relative to the mean path length for collision in liquid hydrogen, a direct determination of the hyperon-nucleon interaction from a study of hyperon-proton collision is very difficult... At the present the most information bearing on hyperon-nucleon interaction is that obtained from the binding of $\Lambda$ hyperon to nuclei (Dalitz, 1965, p. 1).

$\Lambda$-hypernuclei are studied in more detail than the other hypernuclei, since the lifetime of $\Lambda$-hyperon is longer than the others, and also because it decays into two well measurable charged particles. Another reason is the absence of coulomb scattering interference for $\Lambda-p$ interactions (Alexander Karshon, 1967). These considerations make the binding energy of $\Lambda$-particles an attractive topic of investigation.

The Baryon-Baryon Interaction

The large binding energies of $\Lambda$-hyperons show that the strength of the $\Lambda$-nuclear interactions are comparable to NN
interactions. The absence of $\Lambda N$ bound state though, together with the fact that the binding energy of the lightest $^{3}_A\Lambda H$ is only slightly larger than that of deuteron indicates that $\Lambda$-binding energies although strong are still substantially weaker than nucleon-nucleon interactions (Bodmer, 1967).

The most characteristic feature of hypernuclei stems from the distinguishability of the hyperon from nucleons, and consequently the absence of Pauli principle for hyperons. Besides this, one big difference between hyperon-nucleon and nucleon-nucleon interaction is the effective range of these forces. NN and YN forces are both transmitted through the meson field. The range of NN force is divided into three regions. The long ranges, $r \approx 2$ fm or more, are dominated by the exchange of single $\pi$-meson. This is the part of NN interaction which is best understood. Then there is the intermediate range of $r \approx 1$ fm, which is attributed to the $\sigma$-mesons that simulates contributions arising from exchange of pairs of $\pi$-mesons. The third region of $r \leq 0.5$ fm and less, is referred to as the "hard core" arising from heavy meson exchange (Barenger, 1969).

$AN$ forces on the other hand, do not have the one pion exchange (OPE) tail, or the longer range of the NN forces. The $N-N$ forces of the longest range is about $0.7$ fm, and corresponds to the intermediate, imperfectly understood part of the NN interaction. As mentioned above one explains this region either by using two pion exchange or one boson exchange (OBE) models (Bodmer, 1967). The two pion exchange is made possible through the following decays:
Absorption of these pions by a neighbouring nucleon will give rise to the .7 fm ΛN interaction. Some typical two pion exchange (TPE) processes are shown in the following graphs (Dalitz, 1965, p. 62).

Other YN interactions also arise from exchange of k, p, ω and other mesons and resonant states which may exist (Dalitz, 1965, p. 76). (The k-meson exchange involves the transfer of strangeness between baryons and give rise to exchange potentials, having a range of ≈ .4 fm).

Finally, the above decays will lead to another possibility, the three body force, which is due to the absorption of pions by two
neighbouring nucleons (Dalitz, 1965, p. 3; Gal et al., 1970).

\[ \text{Figure 5. The pionic component of the ANN three body potential.} \]

It will be seen in the present calculations that these three body potentials should not be overlooked and they could have appreciable contribution to the binding energies (de—Shalit, 1967, p.5; Gal et al., 1977).

The Overbinding Problem

Interest in $\Lambda$—particle studies is increased recently in attempts to explain and reproduce the important features of strangeness exchange ($K^-$, $\pi$) reactions on a number of targets (Auerbach & Van Giai, 1979; Dalitz & Gal, 1978; Dalitz, 1981). In an article by D. Halderson (1984), some problems pertaining to the hypernuclear structure calculations are mentioned and a solution is offered. Namely, the fact that the hyperon wavefunction is different from that of nucleon, and also elimination of spurious center of mass excitations for hyperon orbitals other than $0s_{1/2}$ are taken into consideration (Dalitz & Gal, 1981; Halderson, 1984). Then calculations are made for $^6\text{Li}$, $^7\text{Li}$, and $^{16}\text{O}$.

In these calculations an interaction of the form:
\[ v_{\text{AN}} = v(x)(1-s+ep_x)(1+a_nx) \]

is employed in which \( p_x \) is the space exchange operator and \( s \) and \( a \) are parameters chosen to fit data (Auerbach et al., 1983). The radial dependence \( v(r) \) for the present calculation is:

\[ v(r) = 4000 y(r/r_1) - 1358.05 y(r/r_2) \]

where \( y(x) = e^{-x}/x \), and \( r_1 = 0.25 \text{ fm} \), and \( r_2 = 0.4 \text{ fm} \). These values provide self consistency in the \( \Lambda \)-single particle energy.

A small symmetric spin-orbit odd interaction is added in the form (Halderson, 1984):

\[ v_{\text{AN}}^{s0} = [-713.5 y(r/r_1) - 81.9 y(r/r_2)] \tilde{l} \tilde{s} \]

The \( l_{\Lambda} = 1 \) levels inferred from \((K,n)\) are well reproduced, but the \( l_{\Lambda} = 0 \), the ground state of \(^{16}\Lambda \) is overbound by 6 MeV, indicating a density dependence in the effective \( \text{AN} \) interaction in the interior of the heavier system.

In this thesis an effort is made to improve the overbinding problem of \(^{16}\Lambda \) ground state. Corrections to the \(^{16}\Lambda \) effective interaction are introduced by a proper Pauli operator. The role of Pauli operator in effective interaction is discussed in the next section.
CHAPTER II

GOLDSTONE-BRUECKNER THEORY

Effective Interactions

To solve the many-body problem of particles inside the nucleus, one may start by solving a non-relativistic Schrödinger equation for particles interacting through a two-body potential. Together with the explicit assumption of non-relativistic limit for the problem, it is also assumed that three-body and four-body potentials are negligible (Day, 1967). The mesonic degrees of freedom are included only as a resulting $\Lambda N$ potential.

A criterion for a realistic two-body potential is the ability to reproduce the shell model properties of the nuclei. In shell model, the many-body problem of nucleons inside nuclei is solved by replacing the interaction of one particle with the rest, with the potential of single particle in an effective average central field due to the rest of the nucleons (de-Shalit & Talmi). Here though, we have to start with a realistic two-body force and hope to calculate the shell model wave functions and the effective potential.

There are some difficulties in nucleon-nucleon interaction however; mainly the hard core, which makes a self-consistent approach difficult. This interaction is also too strong to use ordinary perturbation techniques directly. However, the presence of many nucleons permits one to introduce an effective nucleon-
nucleon interaction which is well behaved and finite. One important
effective interaction is the $G$-matrix, or reaction matrix central to
Brueckner-Goldstone theory of nuclear matter (Ring & Schunck, 1980,
chap. 4).

Goldstone Theorem

Goldstone theorem gives the perturbation expansion of the exact
ground state function and the exact ground state energy of a many-
fermion system (Baranger, 1969; Day 1967). The Hamiltonian is the
sum of kinetic energies of all the particles plus the sum of two-
body interactions between them:

$$ H = \sum_i A_i T_i + \sum_{i<j} V_{ij}, $$

in which $V_{ij}$ is the realistic two-body force. $H$ is divided into a
perturbed and an unperturbed part:

$$ H = H_0 + H_1, $$

where $H_0 = \sum_i (T_i + U_i)$ and $H_1 = \sum_{i<j} V_{ij} - \sum_i U_i$.

Inclusion of the single particle potential $U$, in the unperturbed
Hamiltonian permits one to make the perturbation $H_1$ very small.
Still, the total Hamiltonian does not involve $U$ and final result
will not depend on $U$, but the energy which is an expansion in powers
of $H_1$ will converge more rapidly for certain choices of $U$. This
particular choice will be discussed in calculation section.

For the unperturbed part one can write:

$$ (T_i + U_i) \tilde{\phi}_p (\mathbf{r}_i) = E_p \tilde{\phi}_p (\mathbf{r}_i) $$

Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.
where $\Phi_p$ are single particle wave functions and form a complete orthonormal set. The unperturbed ground state is the normalized $\Phi_o$ represented by a Slater determinant:

$$\Phi_o = (A!)^{-1/2} \varphi (\Phi(r_1) ... \Phi(r_A))$$

where $\varphi$ is antisymmetrizing operator. Then,

$$H_o \Phi_o = \varepsilon_0 \Phi_o, \quad \varepsilon_0 = \sum_{n=1}^{A} E_n$$

The exact ground state satisfies: $H \Psi = \varepsilon \Psi$. The expansion for $e$ through third order in $H_1$ is:

$$\Psi = \varepsilon_0 + \langle \Phi_o | H_1 | \Phi_o \rangle + \langle \Phi_o | H_1 (\varepsilon_0 - H_o) \Phi_o | \Phi_o \rangle$$

$$- \langle \Phi_o | H_1 (\varepsilon_0 - H_o) \Phi_o | \Phi_o \rangle + \langle \Phi_o | H_1 (\varepsilon_0 - H_o) \Phi_o | \Phi_o \rangle \Phi_o \rangle ...$$

where $P = 1 - |\Phi_o \rangle \langle \Phi_o|$ is the projection operator which restricts the summation over intermediate states so that it contains only states above Fermi sea (Day, 1967). The matrix elements of $H_1$ would involve terms such as $\langle \Phi_i \Phi_i | v_{ij} \Phi_j \Phi_j \rangle$. As it stands the matrix elements can get very large because of the hard core.

**Brueckner Reaction Matrix**

The same kind of problem which arises in the nucleon-nucleon interaction due to the short range repulsion in the nuclei also arises in nucleon-nucleon scattering in free space. Namely, in Goldstone expansion the hard core makes the matrix elements involving a potential infinite, and in the scattering problem, by
using the Born approximation in which one calculates the scattering amplitude to first order in \( v \), one obtains inaccurately large values.

The treatment is also similar for the two cases. In scattering problem, one calculates the scattering amplitude to all orders in \( v \), which amounts to solving the Lippmann-Schwinger equation, including multiple scattering (Joachain, 1975; Merzbacher, 1970; Soga, 1984). Then one gets correct results. In Goldstone expansion, instead of bare interaction, one introduces Brueckner's effective potential which is itself a sum of infinite scattering processes of two nucleons in nuclear matter, the bare interaction being just the Born term of this series (Ring & Schunck, 1980, Chap. 4). So it suffices to do a complete summation of all orders of the interaction for every pair of interacting particles.

Since the interaction is strong only at short ranges, this should be sufficient to ensure convergence and it should not be necessary to sum completely by all interactions between three nucleons interacting at close range, four nucleons etc... (Baranger, 1969, p. 542).

This effective interaction is called G–matrix, or reaction matrix. It is for two nucleons in nuclear matter, but analogous to scattering T–matrix for two nucleon in free space. It is defined in a similar manner, too. So in operator form \( G \) is defined as (Day, 1967):

\[
G(\omega) = v + v \frac{(Q/e)}{v + v \frac{(Q/e)}{v + ...}}
\]

\[
G(\omega) = v + v \frac{(Q/e)}{v + v \frac{(Q/e)}{v + ...}}
\]

\[
G(\omega) = v + v \frac{(Q/e)G(\omega)}{v + v \frac{(Q/e)G(\omega)}{v + ...}}
\]
and this equation is called the Bethe-Goldstone equation. $Q$ and $e$ are two particle operators defined as:

$$Q|pq> = \begin{cases} |pq> & \text{if } p>A \text{ and } q>A \\ 0 & \text{Otherwise} \end{cases}$$

$$e|pq> = (\omega - E_p - E_q)^2 |pq> \text{ stands for } \Phi_p(x_1)\Phi_q(x_2)$$

The Pauli operator annihilates two particle states below Fermi sea. It is for two nucleons and is to be modified for $A$-hyperons. Operator $e$ gives the starting energy $\omega$ minus the energy of the two particle state. It is important to note that $G$ is a function of $\omega$, and $\omega$ must be specified to avoid ambiguity in $G$.

The purpose of this kind of many-body technique is two fold: first, by resumming the series, one gets rid of the hard core problem; second, by elimination of the potential in favor of reaction matrix, one includes more of the many-body effects than if one had taken just the bare interaction.
CHAPTER III

CALCULATIONS

Choice of the Single Particle Potential

The perturbation $H_1$, in the Goldstone expansion was divided into two parts:

$$H_1 = \sum_{i<j} v_{ij} - \sum_i U_i$$

i.e., a two-body and a one-body part. The two-body potential was replaced by the G-matrix in order to get rid of the hard core problem. Now one is to choose the single particle potential $U$.

We recall that the final result is independent of $U$, and inclusion of $U$ in the unperturbed Hamiltonian $H_0$ is intended to ensure a rapid convergence, and to ease the numerical calculations. A convenient choice is harmonic oscillator potential. This fulfills the requirement of the Goldstone theorem, that the particle wavefunctions should form a complete orthonormal set. The main reason for this particular choice is, however, the fact that this $H_0$ nicely splits into a center of mass and a relative part (Baranger, 1969).

G-Matrix for $^{16}_A\text{O}$

As mentioned earlier, the effective $\Lambda N$ interaction for $^{16}_A\text{O}$ should be modified. Since the interaction used for $^6\Lambda\text{Li}$ gives reasonable results, the G-matrix for oxygen is calculated in terms
of that for $^6\text{Li}$ (Halderson, 1984). Both of these matrices should satisfy the Bethe-Goldstone equation: $G(\omega) = v + v(\Omega/e)G(\omega)$.

Let $G_a$ and $G_b$ be matrices satisfying the above equation, and let $a$ and $b$ be arbitrary operators.

$$G_a = v + vaG_a = v + vav + vavav + ...$$

$$G_b = v + vbG_b = v + vbv + vbbv + ...$$

$$= v + v[a + (b-a)]v + v[a + (b-a)]v[a + (b-a)]v + ...$$

So $G_b$ can be expanded completely to include a large number of terms. These terms are now regrouped according to the number of $(b-a)$'s that occur:

**The 0th order:** $v + vav + vavav + ... = G_a$

**The 1st order:** $(v + vav + vavav + ...) (b-a) (v + vav + vavav + ...) = G_a (b-a) G_a$

**The 2nd order:** $(v + vav + vavav + ...) (b-a) (v + vav + vavav + ...) - (b-a) (v + vav + vavav + ...) = G_a (b-a) G_a (b-a) G_a$

$$G_b = G_a + G_a (b-a) G_a + G_a (b-a) G_a (b-a) G_a + ...$$

which is the iterative solution of the equation

$$G_b = G_a + G_a (b-a) G_a.$$  

This equation may now be used with $G_b$ as the corrected oxygen $G$-matrix, $G_a$ the $^6\text{Li}$ $G$-matrix, and $a$ and $b$ as the corresponding $Q/e$ operators (Baranger, 1969).
Treatment of the Pauli Operator and Energy Denominator

The form of operator \( \Omega \) which annihilates a two particle state below Fermi Sea, is governed by different Fermi levels for \( \Lambda \) particle and nucleons. The Fermi Sea, being the lowest filled states, of course differs for various nuclei. It is shown for \(^6\text{Li}\) and \(^{16}\text{O}\) in the following diagrams:

![Diagram showing Fermi levels in \(^6\text{Li}\) and \(^{16}\text{O}\).]

Due to its distinguishability from nucleons, \( \Lambda \)-particle would not obey the Pauli principle and it resides in the \( 0S_{1/2} \) orbit. The Fermi levels for lambda and nucleons in \(^6\text{Li}\) and \(^{16}\text{O}\) are shown in the following diagrams:

![Diagram showing Fermi levels in \(^6\text{Li}\) and \(^{16}\text{O}\).]
Thus the projection operator $Q_0$ for $^6_L^A$ is defined as:

$$Q_0 = \begin{cases} 1 & \text{if } 2n_A + l_A > 0 \text{ and } 2n_N + l_N > 0 \\ 0 & \text{otherwise} \end{cases}$$

For $^16_A^O$, however, the projection operator should annihilate $\Lambda$ from $0S_{1/2}$, which is the same as $Q_0$, and also should annihilate nucleons from $0P_{1/2}$, $0P_{3/2}$ and $0S_{1/2}$. Consequently $Q$ for $^16_A^O$ will be:

$$Q = \begin{cases} 1 & \text{if } 2n_N + l_N > 0 \text{ and } 2n_A + l_A > 0 \\ 0 & \text{otherwise} \end{cases}$$

The other quantity which has to be specified is the energy denominator. $G$ is now written as:

$$G(\omega) = \nu + \nu_0 \left[ \frac{Q}{(\omega - E_0)} \right] G(\omega)$$

$H_0$ is harmonic oscillator Hamiltonian and $H_0 = H_0(N) + H_0(\Lambda)$ with $\hbar\omega_A = 14.05$ MeV for $\Lambda$-particle and $\hbar\omega_N = 11.83$ MeV for nucleon. Due to the pairing interaction, the single particle energy of occupied orbits is lowered by an energy gap $\Delta$ (Cohen, 1971; Soga, 1983). This gap is experimentally observed to be $\approx 30$ MeV, therefore this amount is subtracted from $H_0$ in the denominator i.e., $\omega - (H_0 - \Delta)$ or equivalently added to $\omega$: $\omega + \Delta - H_0$. This also lowers the single particle energy of unoccupied orbits by an amount comparable to that observed for the occupied orbits. $\omega$ is the starting energy $E_0(\Lambda) + E_0(N)$. In the present calculations the following experimental values are used (Dalitz & Gal, 1978, McCarthy & Davies, 1970):
TABLE 1

Experimental values for $E(N) E_0(\Lambda)$, and the energy gap $\Delta$.

$\Delta = 30$ MeV

Redefine $\omega = \omega + \Delta$, to include the energy gap. Thus, $\omega = 9, 3, \text{ and } -9$ Mev corresponding to $0P_{1/2}, 0P_{3/2}, 0S_{1/2}$ orbits respectively.

$G_{Li} (\omega) = v + v [Q_0/(\omega - E_0)] G_{Li} (\omega)$, the G-matrix using $^6_{\Lambda} Li$ Pauli operator is formed first, then equation

$$G_0 = G_{Li} + G_{Li} [Q/(\omega - E_0) - Q_0/(\omega - E_0)] G_0$$

is employed to obtain the improved G matrix with the $^{16}_{\Lambda} O$ Pauli operator.

Binding Energy Calculations

Binding energy is the sum of potential and kinetic energies:

$$B = P.E. + K.E.$$ 

i) Kinetic energy:

From the total energy of the core nucleus and $\Lambda$-particle, the center of mass kinetic energy ($T_{c.m}$) should be subtracted.

$$T = \sum_i P_i^2/2m + P^2_{\Lambda}/2m - T_{c.m}$$
\[ T_{c.m} = \frac{p^2}{2M}, \quad M = Am + m_A \]

where \( m \) and \( m_A \) are the masses of nucleon and \( A \)-particle respectively.

\[ T_{c.m} = \frac{1}{2M} \left[ p_A^2 + \sum_i p_i^2 \right]^2 \]

\[ = \frac{1}{2M} \left[ \sum_{i,j} p_i \cdot p_j + 2 \sum_i p_i \cdot p_A + p_A^2 \right] \]

\[ = \frac{1}{2M} \left[ \sum_i p_i^2 + 2 \sum_{i<j} p_i \cdot p_j + 2 \sum_i p_i \cdot p_A + p_A^2 \right] \]

\[ T = \sum_i \left( \frac{1}{2m} - \frac{1}{2M} \right) p_i^2 + \left( \frac{1}{2m_A} - \frac{1}{2M} \right) p_A^2 - \frac{1}{M} \sum_{k \neq i} p_i \cdot p_k \]

\[ - \frac{1}{M} \sum_i p_i \cdot p_A \]

Now the total Hamiltonian is written as:

\[ H = V_{AN} + V_{NN} + T \]

Substituting \( T \) in this formula and rearranging terms:

\[ H = V_{NN} + V_{AN} + \sum_i \left( \frac{1}{2m} - \frac{1}{2M} \right) p_i^2 + \left( \frac{1}{2m_A} - \frac{1}{2M} \right) p_A^2 \]

\[ - \frac{1}{M} \sum_{k \neq i} p_i \cdot p_k - \frac{1}{M} \sum_i p_i \cdot p_A \]

\[ = V_{NN} + \sum_i \left( \frac{1}{2m} - \frac{1}{2M} \right) p_i^2 - \frac{1}{2M} \sum_i p_i^2 - \frac{1}{M} \sum_{k \neq i} p_i \cdot p_j \]

\[ + V_{AN} - \frac{1}{(m + Am)} \sum_i p_i \cdot p_A \]

\[ + \left( \frac{1}{2m_A} - \frac{1}{2M} \right) p_A^2 \]

(3-1): 

\[ V_{NN} + \sum_i \left( \frac{1}{2m} - \frac{1}{2M} \right) p_i^2 - \frac{1}{2M} \sum_i p_i^2 - \frac{1}{M} \sum_{k \neq i} p_i \cdot p_j \]

\[ = V_{NN} - \frac{1}{M} \sum_{k \neq i} p_i \cdot p_j + \left[ \frac{m_A}{(M_{core} + m_A)} \right] \sum_i p_i^2/2m \]
\[ V_{NN} = \frac{1}{M} \sum_{i} \frac{A}{(m^2_A + m^2)} \cdot p_i \cdot p_j + \left( m_A/(m_{\text{core}} + m_A) \right) \left( \frac{3}{4} \hbar \omega \right) \]

(3-2) : \[ V_{AN} = \frac{1}{(m_A + Am)} \sum_i p_i \cdot p_A \] is the \( H_{AN} \) term.

(3-3) : \[ (\frac{1}{2} m_A - 1/2M) p_A^2 \]

\[ = (Am) \frac{p_A^2}{(m_A + Am) 2m} \]

\[ = \left( m_{\text{core}}/(m_{\text{core}} + m_A) \right) \left( \frac{3}{4} \hbar \omega \right). \]

since the \( A \) is assumed to reside in a \( 0S_{1/2} \) state.

Terms contributing to the \( A \) KE in this Hamiltonian are:

\[ KE = \left[ m_A / (m_{\text{core}} + m_A) \right] \left( \frac{3}{4} \hbar \omega \right) + \left[ m_{\text{core}} / (m_{\text{core}} + m_A) \right] \left( \frac{3}{4} \hbar \omega \right) \]

ii) Potential energy:

Potential energy is found to be [See Appendix]:

\[ PE = \sum_{J\text{Jm}_A} V_{j} J [J] - \sum_{J}\sum_{j_h j} (-)^{2j_h + 2j} [J] \left\{ \begin{array}{ccc} j_h & j & J \\ j_h & j & J_B \end{array} \right\} \]

in which the first term is due to the binding of \( A \)-particle to \( 160 \) core and the second term corresponds to that of \( A \) with the hole that should be subtracted.
CHAPTER IV

RESULTS

\[ KE = \left[ m_A/(m_A + M_{\text{core}}) \right] (3/4 \, \hbar \omega_N) + \left[ M_{\text{core}}/(M_{\text{core}} + m_A) \right] (3/4 \, \hbar \omega_A) \]

with \( m_A = 1115 \, \text{MeV} \), \( M_{\text{core}} = (931 \times 15) \, \text{MeV} \), \( \hbar \omega_N = 11.83 \, \text{MeV} \) and \( \hbar \omega_A = 14.05 \, \text{MeV} \).

\[ KE = 10.4144 \, \text{MeV} \]

\[ PE = \sum_{J, \ell} (J \mid \ell) - \sum_{J} (j_{h}^{\ell}, j_{h}^{\ell}) (-1)^{2j+h} \begin{bmatrix} j_h & j & J \end{bmatrix} \begin{bmatrix} j_h & j & J \end{bmatrix} \]

For \(^{16}O\), \(J_B = 1\) and :

\[ PE = 2 \langle 0S_{1/2} \ 0S_{1/2} \ (0) \mid V \mid 0S_{1/2} \ 0S_{1/2} \rangle^{1/2} + 2 \langle 0S_{1/2} \ 0S_{1/2} \ (1) \mid V \mid 0S_{1/2} \ 0S_{1/2} \rangle^{3/2} + 2 \langle 0P_{3/2} \ 0S_{1/2} \ (1) \mid V \mid 0P_{3/2} \ 0S_{1/2} \rangle^{3/2} + 2 \langle 0P_{3/2} \ 0S_{1/2} \ (2) \mid V \mid 0P_{3/2} \ 0S_{1/2} \rangle^{5/2} + 2 \langle 0P_{1/2} \ 0S_{1/2} \ (0) \mid V \mid 0P_{1/2} \ 0S_{1/2} \rangle^{1/2} + 2 \langle 0P_{1/2} \ 0S_{1/2} \ (1) \mid V \mid 0P_{1/2} \ 0S_{1/2} \rangle^{3/2} - \sum_{J} \langle 0P_{1/2} \ 0S_{1/2} \ (J) \mid V \mid 0P_{1/2} \ 0S_{1/2} \rangle \begin{bmatrix} 1/2 \ 1/2 \ J \end{bmatrix} \begin{bmatrix} 1/2 \ 1/2 \ 1 \end{bmatrix} \]

(4-1) is expanded as:

\[ \langle 0P_{1/2} \ 0S_{1/2} \ (0) \mid V \mid 0P_{1/2} \ 0S_{1/2} \rangle \begin{bmatrix} 1/2 \ 1/2 \ 0 \end{bmatrix} \begin{bmatrix} 1/2 \ 1/2 \ 1 \end{bmatrix} \]

\[ \langle 0P_{1/2} \ 0S_{1/2} \ (1) \mid V \mid 0P_{1/2} \ 0S_{1/2} \rangle \begin{bmatrix} 1/2 \ 1/2 \ 1 \end{bmatrix} \begin{bmatrix} 1/2 \ 1/2 \ 1 \end{bmatrix} \]

A computer code is developed to calculate the above matrix.

Binding energy of $^{16}_6$O groundstate:

- using $G_{L1}$-matrix
  
  $PE = -24.006535$ MeV  
  $KE = +10.414392$ MeV  
  $BE = -13.59093$ MeV

- using $G_0$-matrix
  
  $PE = -23.58493$ MeV  
  $KE = +10.414392$ MeV  
  $BE = -13.170538$ MeV

$\Delta (BE) = 0.420455$ MeV
CHAPTER V

CONCLUSION

A modified AN interaction is considered for $^{16}_A^0$ in terms of a Brueckner-Goldstone G-matrix with a corrected Pauli operator. Calculations were not sensitive to increase of $n$ from 6 to 8 indicating that convergence is already achieved for $n = 6$. The contribution of Pauli operator correction is found to be about one half MeV. So, the overbinding problem of $^{16}_A^0$ is improved but not corrected completely. This makes the inclusion of repulsive three-body forces more urgent. Since the number of ANN interactions in $^{16}_A^0$ are ten times more than those in $^{6}_A^Li$, these three-body interactions would improve the overbinding in $^{16}_A^0$ without changing the results of $^{6}_A^Li$ drastically.
APPENDIX

The potential energy for $^{\Lambda_0}$ in which one nucleon is replaced by a $\Lambda$-particle involves particle–hole matrix elements of the form:

$$V = \langle j_p, j_h^{-1} | V | j_p', j_h' \rangle J_B$$

$$= \sum \sum_{m_p, m_h, M_B} \langle j_p, j_h^{-1} | V | j_p', j_h' \rangle J_B$$

$$= \langle j_p, m_p | V | j_p', m_h' \rangle \langle j_h, -m_h | V | j_h', -m_h' \rangle$$

C's are the Clebsh–Gordan coefficients ensuring that the total angular momentum $J_B$ is a good quantum number, $(-j_h - m_h)$ and $(-j_h' - m_h')$ ensure correct rotational transformation characteristic of the hole creation operators (Brink & Satchler, 1968/1979). The above matrix element can be written in its second quantized form:

$$\langle j_p, m_p | V | j_p', m_h' \rangle = \frac{1}{2} \sum_{\alpha, \beta, \gamma, \delta} V_{\alpha \beta \gamma \delta} \langle 0 | a_{\alpha}^+ a_{\beta}^+ a_{\gamma}^+ a_{\delta}^+ | 0 \rangle$$

$$= \frac{1}{2} \sum_{\alpha, \beta, \gamma, \delta} V_{\alpha \beta \gamma \delta} \langle 0 | a_{\alpha}^+ a_{\beta}^+ a_{\gamma}^+ a_{\delta}^+ | 0 \rangle$$

$$- \frac{1}{2} \sum_{\alpha, \beta, \gamma, \delta} V_{\alpha \beta \gamma \delta} \langle 0 | a_{\alpha}^+ (\delta h_{\gamma, \delta}^\gamma - a_{\gamma}^+ a_{\delta}^+) | 0 \rangle$$

The contribution of term (A-1) is:
\[
1/2 \sum_{\alpha \beta \gamma \delta} v_{\alpha \beta \gamma \delta} \langle 0 | a_p \frac{a_\alpha^+ a_\beta^+ a_\gamma a_\delta}{a_p^+ | 0 \rangle \delta^2_R \]
\]
\[
= \sum \left[ c_{j_p j_h J_B} \right]^2 \langle 0 | a_p V a_p^+ | 0 \rangle \delta_{j_p} \delta_{j_p'} \]
\]
\[
= 1/2 \sum_{j_in_j_j_a} \langle j_i j_{j_a} | V \langle j_i j_{j_a} - | j_{j_i} j_{j_a} \rangle \delta_{j_i} \delta_{j_i'} \]
\]
\[
+ \sum_{j_i j_{j_a}} \langle j_i j_{j_a} | V \langle j_i j_{j_a} - \rangle \delta_{j_i} \rangle \delta_{j_i'} \]
\]
\[
= \sum_{j_i j_{j_a}} \langle j_i j_{j_a} | J \rangle \delta_{j_i} \delta_{j_i'} \]
\]
\[
= 1/2 \sum_{j_i j_{j_a}} \langle j_i j_{j_a} | J \rangle \delta_{j_i} \delta_{j_i'} \]
\]
\[
= \sum_{j_i j_{j_a}} \langle j_i j_{j_a} | J \rangle \delta_{j_i} \delta_{j_i'} \]
\]
\[
The first term contains interaction of the core with itself and does not contribute to \( A \) binding energy. The second term is the interaction of \( A \)-particle with the core, in which we neglect the exchange term corresponding to the exchange of \( A \) to \( N \) and vice versa. Then contribution from equation (A-1) becomes:
\]
\[
\sum_{j_i j_{j_a}} \langle j_i j_{j_a} | J \rangle \delta_{j_i} \delta_{j_i'} \]
\]
\[
The contribution of term (A-2) is:
\]
\[
= -1/2 \sum_{\alpha \beta \gamma \delta} v_{\alpha \beta \gamma \delta} \langle 0 | a_p \frac{a_\alpha^+ a_\beta^+ a_\gamma a_\delta}{a_p^+ | 0 \rangle \delta^2_R \]
\]
\[
= -1/2 \sum_{\alpha \beta \gamma \delta} v_{\alpha \beta \gamma \delta} \langle 0 | a_p \frac{a_\alpha^+ a_\beta^+ a_\gamma a_\delta}{a_p^+ | 0 \rangle \delta^2_R \delta^2_R \]
\]
\[
+1/2 \sum_{\alpha \beta \gamma \delta} v_{\alpha \beta \gamma \delta} \langle 0 | a_p \frac{a_\alpha^+ a_\beta^+ a_\gamma a_\delta}{a_p^+ | 0 \rangle \delta^2_R \]
\]
\[
+1/2 \sum_{\alpha \beta \gamma \delta} v_{\alpha \beta \gamma \delta} \langle 0 | a_p \frac{a_\alpha^+ a_\beta^+ a_\gamma a_\delta}{a_p^+ | 0 \rangle \delta^2_R \]
\]
\[
\text{Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.}
\]
\[-\frac{1}{2} \sum_{\alpha\beta\gamma} V_{\alpha\beta\gamma} \langle 0|a_{p}^{+} a_{s}^{+} a_{s} a_{p}|0\rangle \delta_{\alpha}^{\alpha} \delta_{\gamma}^{\gamma} \]  \hspace{1cm} (A-6)

\[(A-2) = (A-3) + (A-4) + (A-5) + (A-6) \]

\[-\frac{1}{2} \sum_{\alpha\gamma} \left[ V_{\alpha h y} - V_{h ay} + V_{h ah} \right] \langle 0|\left( \delta_{\alpha}^{p} - a_{\alpha} \right) \left( \delta_{\gamma}^{p} - a_{\gamma} \right) |0\rangle \]

\[-\sum_{\alpha\gamma} \left[ V_{\alpha h y} - V_{h ah} \right] \langle 0|a_{\alpha}^{+} a_{\gamma}^{+} |0\rangle \delta_{\gamma}^{p} \]

\[= - \langle j_{p}^{m_{p}j_{h}^{m_{h}}} | V[j_{p}^{m_{p},j_{h}^{m_{h}}} - j_{h}^{m_{h},j_{p}^{m_{p}}} ] \rangle \]

\[\sum_{j_{c}^{m_{c}}} \langle j_{c}^{m_{c}} | V[j_{c}^{m_{c},j_{h}^{m_{h}}} - j_{h}^{m_{h},j_{c}^{m_{c}}} ] \rangle \delta_{\gamma}^{p} \]

The second term is the interaction of hole with the core, and again will be neglected since it does not contribute to the \(\Lambda\) binding energy. The first term is the \(\Lambda\) hole interaction and should be subtracted from the \(\Lambda\)-core interaction found in \((A-1)\).

The contribution from \((A-2)\) is thus:

\[\langle j_{h}^{m_{h},j_{p}^{m_{p}}} | V[j_{h}^{m_{h},j_{p}^{m_{p}}} - j_{p}^{m_{p},j_{h}^{m_{h}}} ] \rangle \]

\[= - \sum_{j_{c}^{m_{c}}} \sum_{j_{c}^{m_{c}}} \langle j_{p}^{j_{h}^{j_{B}}} | j_{h}^{j_{B}^{J}} \rangle \sum_{j_{c}^{m_{c}}} \sum_{j_{c}^{m_{c}}} \langle j_{c}^{m_{c},j_{p}^{m_{p}}} | j_{h}^{m_{h},j_{c}^{m_{c}}} \rangle \]

\[\langle j_{h}^{j_{p}^{j(J)}}, V[j_{h}^{j_{p}^{j(J)}}, -j_{p}^{j^{j_{p}^{j(J)}}} -j_{h}^{j_{h}^{j_{p}^{j(J)}}} | j_{h}^{j_{p}^{j(J)}} \rangle \]

(A-7)

Again in the matrix element, \((A-7)\), the exchange term is dropped.

Thus \((A-2)\) is:

\[\sum_{J} (A-7) \sum_{m_{c}} [J_{B}] [J] (\pm j_{h}^{j_{p}^{j_{h}^{j_{p}^{j_{h}^{j_{p}^{j_{h}}}}} - j_{p}^{j_{h}^{j_{p}^{j_{h}^{j_{p}^{j_{h}}}}}} - j_{h}^{j_{p}^{j_{h}^{j_{p}^{j_{h}}}}}] \]

where Clebsch–Gordan coefficients are written in terms of 3-j symbols
(Messiah, 1966)

\[
\begin{pmatrix}
  j_p & j_h & j_B \\
  m_p & m_h & m_B
\end{pmatrix}
\begin{pmatrix}
  j'_p & j'_h & j'_B \\
  m'_p & m'_h & m'_B
\end{pmatrix}
\begin{pmatrix}
  j_h & j_p & j \\
  m_h & m_p & m
\end{pmatrix}
\]

(A-2):

\[
-\sum_{J} \langle J \rangle^{(-)-j_p+j_h+j_p'} \frac{1}{[J_{\mathbb{S}}]} \left\{ \begin{array}{c}
  j_p \\
  j_h \\
  j_B
\end{array} , \begin{array}{c}
  j'_p \\
  j'_h \\
  j'
\end{array} \right\} \langle j'_h, j_p(J) | j' | j_h, j_p'(J) \rangle
\]

Here the 3-j symbols are written in terms of Racah coefficients
(Messiah, 1966). Therefore contribution from (A-2) becomes:

\[
-\sum_{J} \langle J \rangle^{(-)-j_p+j_h+j_p'} \left\{ \begin{array}{c}
  j_p \\
  j_h \\
  j_B
\end{array} , \begin{array}{c}
  j'_p \\
  j'_h \\
  j'
\end{array} \right\} \langle j'_h, j_p(J) | j' | j_h, j_p'(J) \rangle
\]

Thus contribution of (A-1) and (A-2) to the potential energy of A-
particle are:

\[
\sum_{J} \frac{\langle J \rangle}{j_c m_{cJ} [j_p]} \langle j_p, j_c (J) | j' | j_c > s_{R'}^2
\]

\[
-\sum_{J} \langle J \rangle^{(-)-j_p+j_h+j_p'} \left\{ \begin{array}{c}
  j_p \\
  j_h \\
  j_B
\end{array} , \begin{array}{c}
  j'_p \\
  j'_h \\
  j'
\end{array} \right\} \langle j'_h, j_p(J) | j' | j_h, j_p'(J) \rangle
\]
